All configurations in this file are based on " Installation and configuration of single node (VirtualBox+Ubuntu+Hadoop+Spark).doc"

1.We strongly recommend you to follow our instruction "Installation and configuration of single node(VirtualBox+Ubuntu+Hadoop+Spark).doc" to avoid problems about environment and configuration.

2.Memory > 1GB

3.If you are running VirtualBox on Windows 8 and it is extremely slow, please refer to this:

http://askubuntu.com/questions/4575

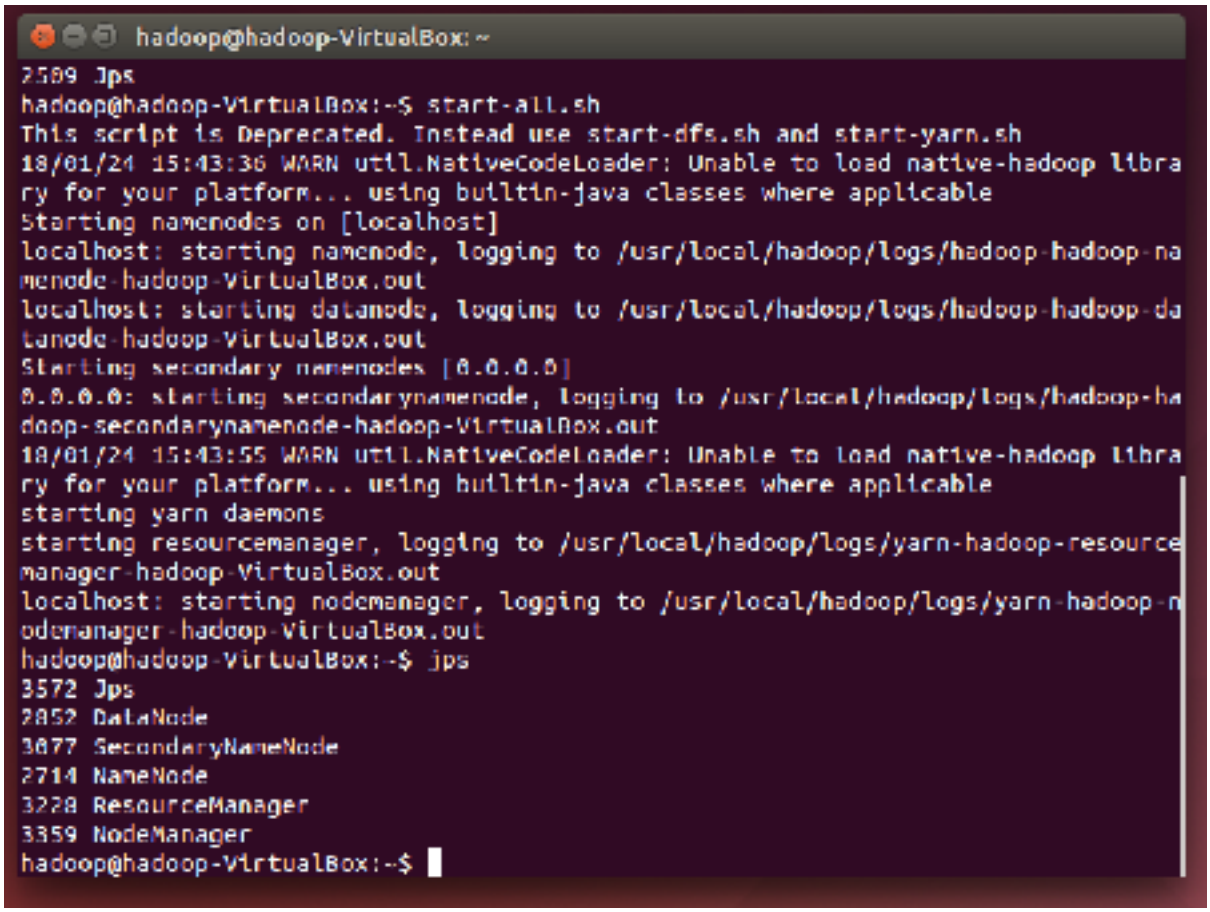
4.Using eclipse can make it easier for you to write some hadoop/mapreduce code.

1.Download eclipse

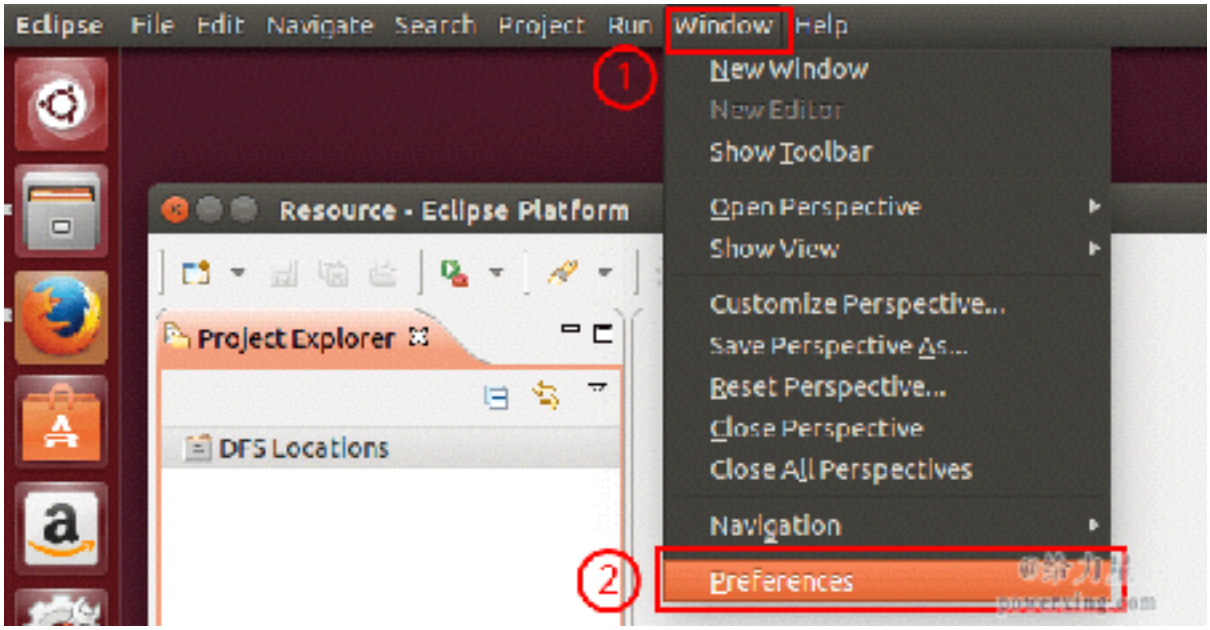
2.Put "hadoop-eclipse-plugon-2.7.4.jar"(because our Hadoop is 2.7.4) into eclipse/dropins.

3.Restart eclipse (make sure you have started the hadoop)

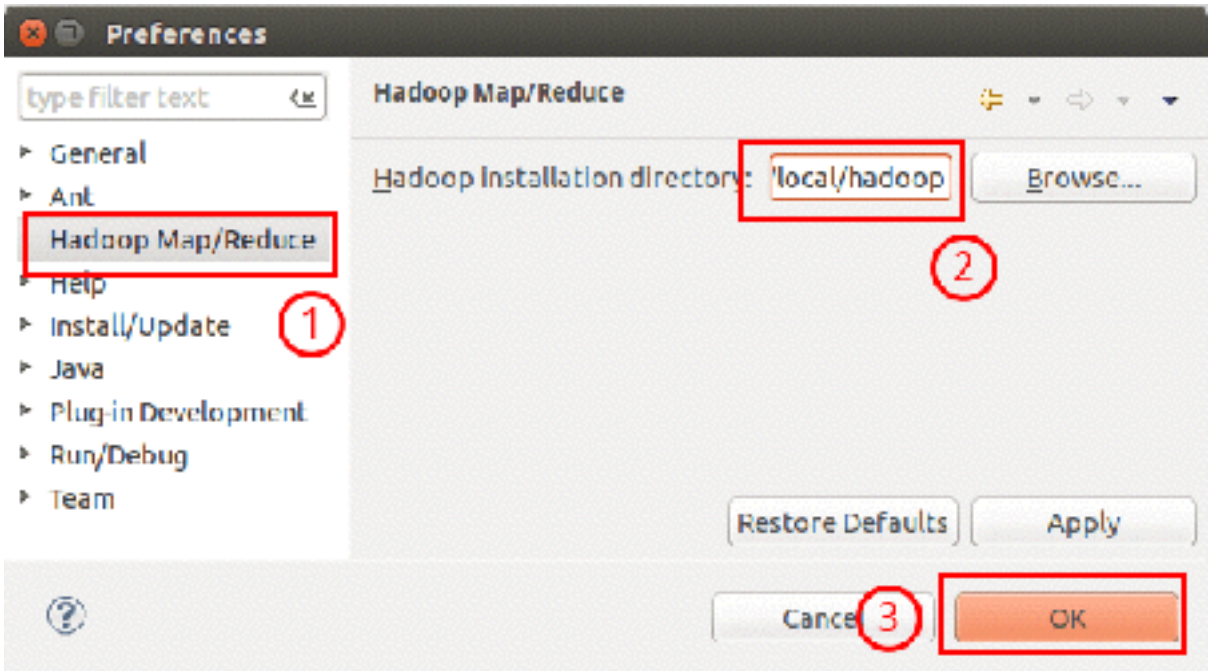
You will see the dfs locations



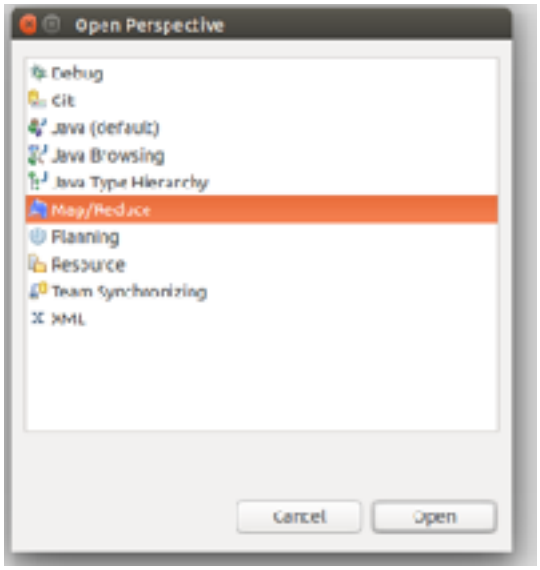
4.click "Windows" then "preferences"



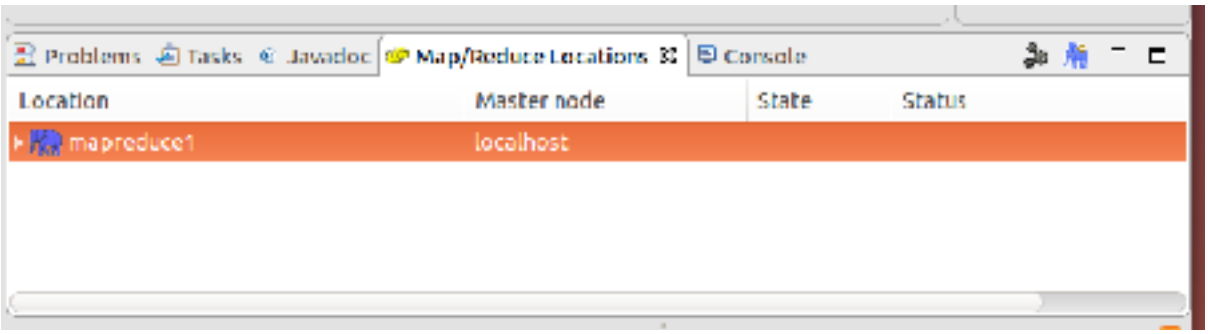
5.Choose your hadoop's path



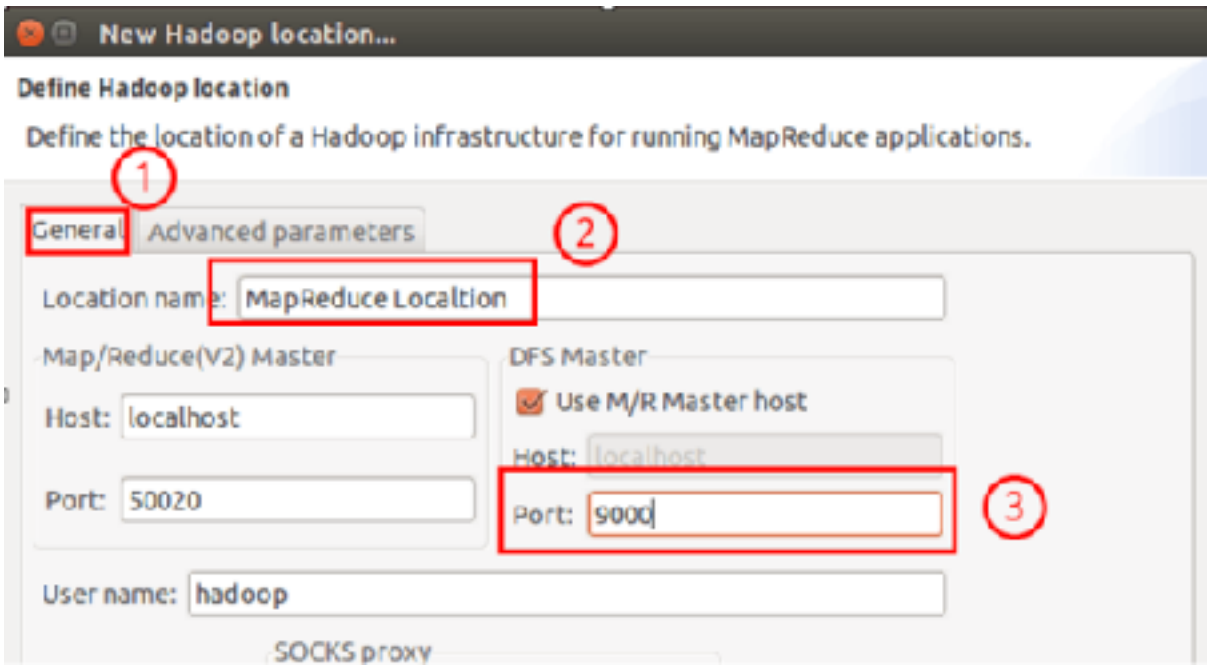
6.click "windows"—>"perspective"—>"open perspective"—>"other"—>"Map/Reduce"



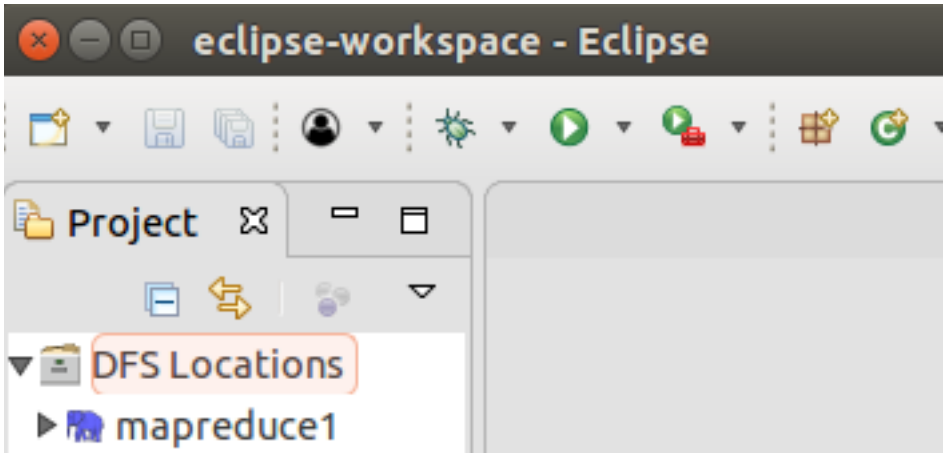
7.connect to hadoop , right click the window below the Map/Reduce Location,choose New Hadoop Location



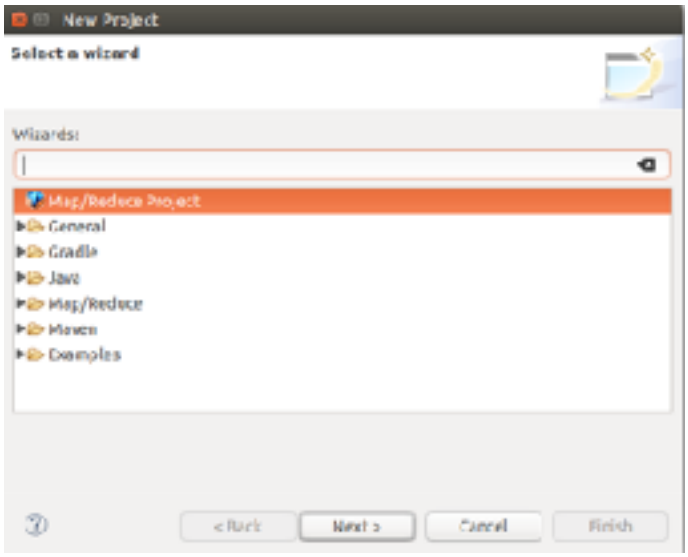
8.choose the location name, fill up the DFS Master port (if you follow our" Installation and configuration of single node (VirtualBox+Ubuntu+Hadoop+Spark).doc" here you need to write 9000)



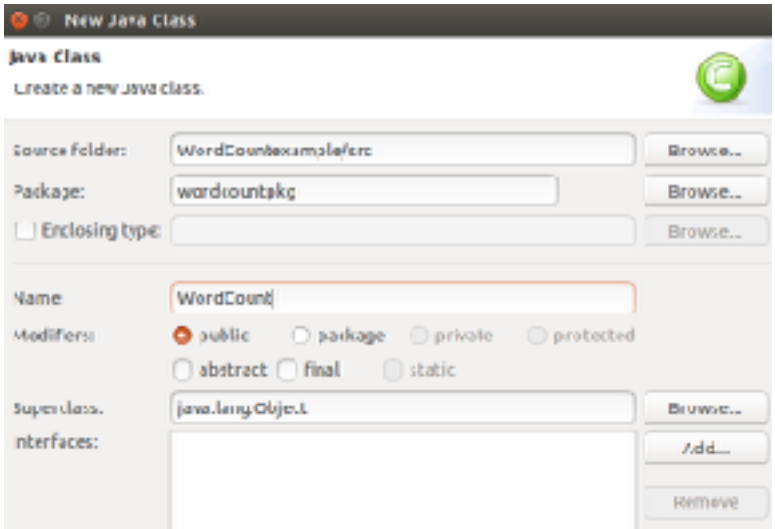
9.then you can see a blue elephant!



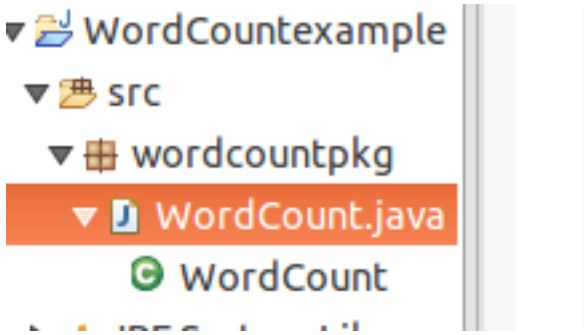
10. Now you can create a project click file—>new—>project—>Map/Reduce Project—>next —> Project name—>finish. You can see your project now.



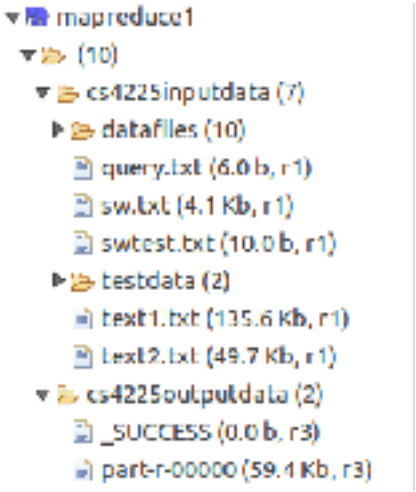
11. Right Click your project—> new —>class, you need to fill up the package and name



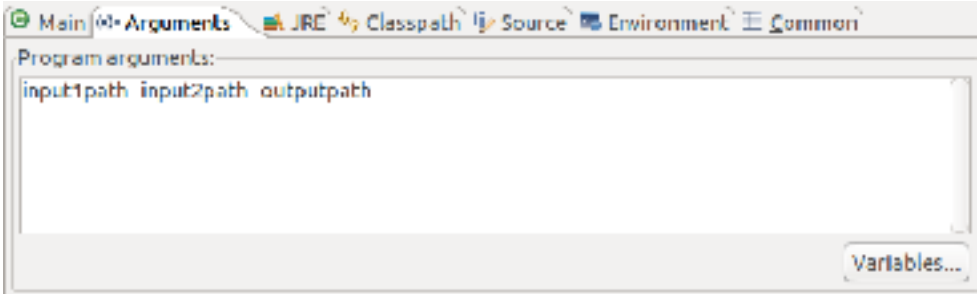
12.copy WordCount.java into your java file.(you need to change some details if using different configuration like paths)



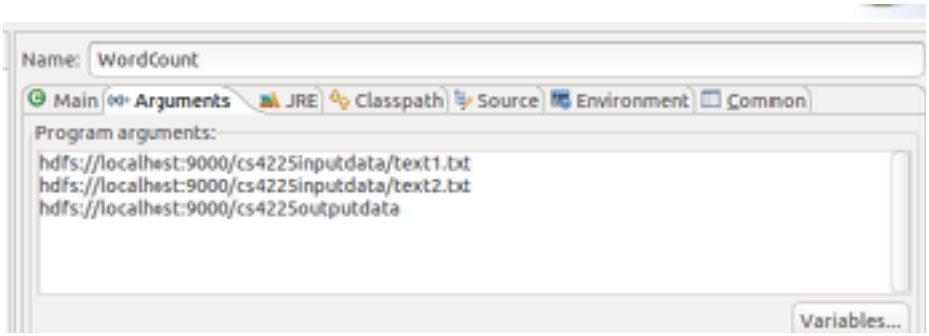
13.using hadoop commands (put) to put our data into hdfs (like: hadoop fs -put data1.txt /data/inout) you can find them here (need to refresh after every operation)

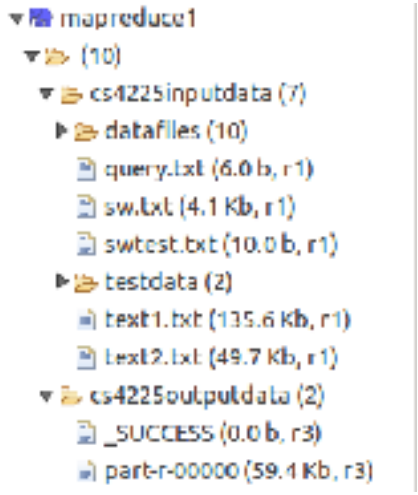


14.right click your java file —>run as—>run configurations—>Arguments



Here you need to fill up your arguments, for example:





15 . run and you will see the result.
